Introduction

The DLLR Series Mini Digital Output Pressure Sensors from All Sensors utilize proprietary CoBeamTM Technology, which minimizes package stress sensitivity and delivers superior long-term stability and enhanced position sensitivity. This advanced dual-die architecture sets a new standard in precision for low-pressure digital sensing applications.

Each sensor is factory-calibrated and programmed with extra compensation terms, enabling system firmware to eliminate high-order linearity errors and achieve highly accurate pressure output. For applications subject to temperature fluctuations, additional thermal compensation minimizes temperature-induced drift and enhances measurement reliability.

Designed for easy integration, the DLLR Series features a digital interface compatible with a wide range of process control, medical, HVAC, and industrial automation systems. Direct serial communication allows for seamless system connectivity, while ultra-low power sleep modes make the series ideal for battery-operated and portable devices.

The DLLR Series is available in miniature packages and delivers stable, accurate performance over a broad temperature range. These sensors are optimized for use with non-corrosive, non-ionic media, including air and dry gases, and offer a compact, reliable solution for today's demanding pressure sensing applications.

DLLR Series High Accuracy Pressure Sensors

Features	Applications
Pressure Ranges of 10 & 30 inH2O	Medical Breathing
• 1.68V to 3.6V Supply Voltage Range	• Environmental Controls
• I2C or SPI Interface (Automatically Selected)	• HVAC
Better Than 0.10% Accuracy	• Industrial Controls
 High Resolution 16/17/18 Bit Output 	Portable / Hand-Held Equipment
 Oversampling Options for Noise Reduction 	

Standard Pressure Ranges

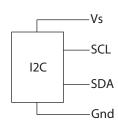

Device	Operating	Operating Range ^A		Proof Pressure		ressure	Nominal Span

Pressure Output Transfer Function

$$Pressure(inH_2O) = 1.25 \times \left(\frac{P_{dig} - OS_{dig}}{2^{24}}\right) \times FSS(inH_2O)$$

Where:

 P_{dia} Is the sensor 24-bit digital output, following corrections applied by extended

compensation.

 OS_{dig} Is the specified digital offset

For Gage Operating Range sensors: $0.1 * 2^{24}$ For Differential Operating Range sensors: $0.5 * 2^{24}$

 $FSS(inH_2O)$ The sensor Full Scale Span in inches H_2O

For Gage Operating Range sensors: Full Scale Pressure
For Differential Operating Range sensors: 2 x Full Scale Pressure

Temperature Output Transfer Function

Temperature (°C) =
$$\left(\frac{Tout_{dig} * 125}{2^{24}}\right) - 40$$

Where:

 $Tout_{dia}$ The sensor 24-bit digital temperature output.

Specification Notes

- NOTE 1: THE SPAN IS THE ALGEBRAIC DIFFERENCE BETWEEN FULL SCALE DECIMAL COUNTS AND THE OFFSET DECIMAL COUNTS. THE FULL SCALE PRESSURE IS THE MAXIMUM POSITIVE CALIBRATED PRESSURE.
- NOTE 2: TOTAL ERROR BAND (TEB) IS THE COMBINATION OF ERRORS INCLUDING OFFSET, SPAN, LINEARITY, PRESSURE HYSTERESIS, TEMPERATURE EFFECT ON OFFSET, AND TEMPERATURE EFFECT ON SPAN.
- NOTE 3: ACCURACY INCLUDES PRESSURE HYSTERESIS, REPEATABILITY AND BEST-FIT STRAIGHT LINE LINEARITY, EVALUATED AT 25C.
- NOTE 4: PARTS PER MILLION OF FULL-SCALE SPAN PER DEGREE C.
- NOTE 5: PARAMETER IS CHARACTERIZED AND NOT 100% TESTED.
- NOTE 6: EVALUATED FOLLOWING CORRECTIONS DESCRIBED IN EXTENDED COMPENSATION SECTION.
- NOTE 7: DATA UPDATE TIME IS EXCLUSIVE OF COMMUNICATIONS, FROM COMMAND RECEIVED TO END OF BUSY STATUS. THIS CAN BE OBSERVED AS EOC PIN LOW- STATE DURATION.
- NOTE 8: AVERAGE CURRENT CAN BE ESTIMATED AS: ICC_{Idle} + (t_{DU} / Reading Interval) * ICCACTIVE). REFER TO FIGURE 2 FOR ACTIVE AND IDLE CONDITIONS OF THE SENSOR (THE ACTIVE STATE IS WHILE FOC PIN IS LOW)
- NOTE 9: THE SENSOR IS CALIBRATED WITH A 3.3V SUPPLY HOWEVER, AN INTERNAL REGULATOR ALLOWS A SUPPLY VOLTAGE OF 1.68V TO 3.6V TO BE USED WITHOUT AFFECTING THE OVERALL SPECIFICATIONS. THIS ALLOWS DIRECT OPERATION FROM A BATTERY SUPPLY.
- NOTE 10: DELAY BETWEEN END OF MEMORY READ REQUEST COMMUNICATION AND START OF MEMORY DATA READ COMMUNICATION.

Device Ordering Options

Output Resolution

Calibrated output resolution can be ordered to be 16, 17, or 18 bits.

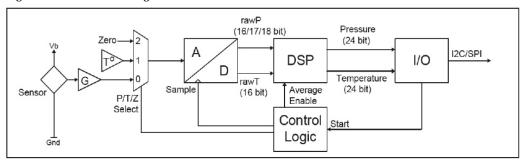

Higher resolution results in slower update times; see the Data Update Time in the Performance Characteristics table.

Operation Overview

The DLLR is a digital sensor with a signal path that includes a sensing element, a variable- bit analog to digital converter, a DSP and an IO block that supports either an I2C or SPI interface (see Figure 1 below). The sensor also includes an internal temperature reference and associated control logic to support the configured operating mode. Since there is a single ADC, there is also a multiplexer at the front end of the ADC that selects the signal source for the ADC.

Figure 1 - DLLR Block Diagram

The ADC performs conversions on the raw sensor signal (P), the temperature reference (T) and a zero reference (Z) during the ADC measurement cycle.

The DSP receives the converted pressure and temperature information and applies a multi-order transfer function to compensate the pressure output. This transfer function includes compensation for span, offset, temperature effects on span, temperature effects on offset and second order temperature effects on offset. There is also linearity compensation for gage devices and front to back linearity compensation for differential devices. This compensated output is further improved by applying additional external correction, as described later in the Extended Compensation instructions section.

<u>Sensor Commands:</u> Five Measurement commands are supported, returning values of either a single pressure / temperature reading or an average of 2, 4, 8, or 16 readings. Each of these commands wakes the sensor from Idle state into Active state, and starts a measurement cycle. For the Start-Average commands, this cycle is repeated the appropriate numper of times, while the Start-Single command performs a single iteration. When the DSP has completed calculations and the new values have been made available to the I/O block, the sensor returns to Idle state. The sensor remains in this low-power state until another Measurement command is received.

After completion of the measurement, the result may then be read using the Data Read command. The ADC and DSP remain in Idle state, and the I/O block returns the 7 bytes of status and measurement data. See Figure 2, following. At any time, the host may request current device status with the Status Read command. See Table 1 for a summary of all commands.

For optimum sensor performance, All Sensors recommends that Measurement commands be issued at a fixed interval by the host system. Irregular request intervals may increase overall noise on the output.

Furthermore, if reading intervals are much slower than the Device Update Time, using the Averaging commands is suggested to reduce offset shift. This shift is constant with respect to time interval, and may be removed by the application. For longer fixed reading intervals, this shift may be removed by the factory on special request.

<u>I/O Interface Configuration:</u> The sensor automatically selects SPI or I2C serial interface, based on the following protocol: If the /SS input is set low by the host (as occurs during a SPI command transaction), the I/O interface will remain configured for SPI communications until power is removed. Otherwise, once a valid device address and command have been received over the I2C interface, the I/O interface will remain configured for I2C until power is removed.

NOTE: The four-pin (SIP) packages only support the I2C interface.

Digital Interface Command Formats

When requesting the start of a measurement, the command length for I2C is 1 byte, for SPI it is 3 bytes.

When requesting sensor status over I2C, the host simply performs a 1-byte read transfer.

When requesting sensor status over SPI, the host MUST send the Status Read command byte while reading 1 byte.

When reading sensor data over I2C, the host simply performs a 7-byte read transfer.

When reading sensor data over SPI, the host MUST send the 7-byte Data Read command while reading the data.

SENDING UNDOCUMENTED COMMANDS TO SENSOR WILL CORRUPT CALIBRATION AND IS NOT COVERED BY WARRANTY.

See Table 1 below for Measurement Commands, Sensor Data read and Sensor Status read details.

Table 1 - DLLR Sensor Command Set

Measurement Commands								
Description	SP	। (3 byte	I2C (1 byte)					
Start-Single	0xAA	0x00	0x00	0xAA				
Start-Average2	0xAC	0x00	0x00	0xAC				
Start-Average4	0xAD	0x00	0x00	0xAD				
Start-Average8	0xAE	0x00	0x00	0xAE				
Start-Average16	0xAF	0x00	0x00	0xAF				

	Read Sensor Data								
I2C	Read of 7 bytes from device								
	Read of 7 bytes from device Host must send [0xF0], then 6 bytes of [0x00] on MOSI Sensor Returns 7 bytes on MISO								

	Read Sensor Status							
I2C	I2C Read of 1 byte from device.							
SPI	Read of 1 byte from device Host must send [0xF0] on MOSI							
	Sensor Returns 1 byte on MISO							

Digital Interface Command Formats (Cont'd)

The Memory Read Command is used to retrieve the extended Compensation Coefficients from internal memory of the sensor. Values (A, B, C, and D) are 32-bit signed integers, stored in eight 16-bit registers at addresses 47 through 54. Values TC50H and TC50L are stored in high byte and low byte, respectively, of address 55, as signed 8-bit integers. Value E is an 8-bit signed integer, stored at Low Byte of address 56.

Table 2 - Coefficient Memory Map

Address	47 (0x2F)	48 (0x30)	49 (0x31)	50 (0x32)	51 (0x33)	52 (0x34)	53 (0x35)	54 (0x36)	55 (0x37)	56 (0x38)
Coeff. Word	[AHW]	[ALW]	[BHW]	[BLW]	[CHW]	[CLW]	[DHW]	[DLW]	[TC50H]	[0]
									[TC50L]	[E]

Each Word is stored in form ([High Byte]:[Low Byte]).

To form the complete integers A, B, C, and D, assemble the words in order ([xHW] : [xLW]). For E, the 8-bit low byte represents the complete integer. For TC50H and TC50L, the high byte and low byte, respectively, represent the complete integers.

The sequence of commands to retrieve these values is in the form of a Memory Read Request (See Table 3) followed by a Memory Data Read (See Table 4). Note that the Memory Read Access Time delay must be observed between the request and the read operations.

Table 3 - Memory Read Request Command

Memory Commands: I2C Write or SPI MOSI:								
Description SPI (3 bytes) I2C (1 byte)								
Read Request	<eeprom address=""> (Values 47 -56 only)</eeprom>	0x00	0x00	<eeprom address=""> (Values 47 -56 only)</eeprom>				

It must be emphasized that these commands be used accurately and carefully. Errors in forming or transmitting these commands can result in degraded sensor operation.

Table 4 - Memory Data Read Operation

Read	Read Memory Data						
I2C	Read of 3 bytes from device.						
	Read of 3 bytes from device.						
SPI	Host must send [0xF0], then 2 bytes of [0x00] on MOSI.						
	Sensor returns 3 bytes on MISO.						

Example: I2C Read of Coefficient B:

Write <**0x31**>, and read back: <**Status**> <**BHW**>. (high 16 bits of B, as 2 bytes) Write <**0x32**>, and read back: <**Status**> <**BLW**>. (low 16 bits of B, as 2 bytes)

B = [BHW:BLW], assembling BHW and BLW into a signed 32-bit integer.

Example: SPI Read of Coefficient D:

Write <**0x35**><0x00><0x00>, over SPI MOSI output.

Set output buffer to <0xF0><0x00><0x00>, then perform 3-byte transfer.

Input buffer will then contain: <Status> < DHW $_{(high\ byte)}>$ < DHW $_{(low\ byte)}>$.

Write <0x36><0x00><0x00>, over SPI MOSI output.

Set output buffer to <0xF0><0x00><0x00>, then perform 3-byte transfer.

Input buffer will then contain: <Status> < $DLW_{(high\ byte)}$ > < $DLW_{(low\ byte)}$ >.

D = [DHW:DLW], assembling DHW and DLW into a signed 32-bit integer.

Digital Interface Data Format

For either type of digital interface, the format of data returned from the sensor is the same. For measurement data, the first byte consists of the Status Byte followed by a 24-bit unsigned pressure value and a 24-bit unsigned temperature value. See the Pressure Output Transfer Function and Temperature Output Transfer Function definitions on page 3 for converting to pressure and temperature. Note that the sensor output includes error terms that must be removed in system software. Refer to *'Extended Compensation Instructions Section'* for these computations.

For memory data output, the status byte is followed by the high byte, then low byte of the memory word.

Refer to Table 5 for the measurement data format of the sensor. Table 6 shows the formation of EEPROM-read data, and Table 7 shows the Status Byte definition.

Note that a completed reading without error will return status 0x40.

Table 5 - Measurement Output Data Format

S[7:0]	P[23:16]	P[15:8]	P[7:0]	T[23:16]	T[15:8]	T[7:0]

Bit 0 [LSB]	ALU Error [1 = Error: Pressure Overrange or Underrange]

I2C Interface

12C Command Sequence

The part enters Idle state after power-up, and waits for a command from the bus master. Any of the five Measurement commands may be sent, as shown in Table 1. Following receipt of one of these command bytes, the EOC pin is set to Low level, and the sensor Busy bit is set in the Status Byte. After completion of measurement and calculation in the Active state, compensated data is written to the output registers, the EOC pin is set high, the BUSY bit is cleared and the processing core goes back to Idle state. The host processor can then perform the Data Read operation, which for I2C is simply a 7-byte Device Read.

If the EOC pin is not monitored, the host can poll the Status Byte by repeating the Status Read command, which for I2C is a one-byte Device Read. When the Busy bit in the Status byte is zero, this indicate that valid data is ready, and a full Data Read of all 7 bytes may be performed.

DO NOT SEND COMMANDS TO SENSOR OTHER THAN THOSE DEFINED IN TABLES 1, 3 & 4.

12C Interface (Cont'd)

12C Bus Communications Overview

The I2C interface uses a set of signal sequences for communication. The following is a description of the supported sequences and their associated mnemonics. Refer to Figure 3 for the associated usage of the following signal sequences.

Bus not Busy (I): During idle periods both data line (SDA) and clock line (SCL) remain HIGH.

<u>START condition (ST):</u> A HIGH to LOW transition of SDA line while the clock (SCL) is HIGH is interpreted as START condition. START conditions are always set by the master. Each initial request for a pressure value has to begin with a START condition.

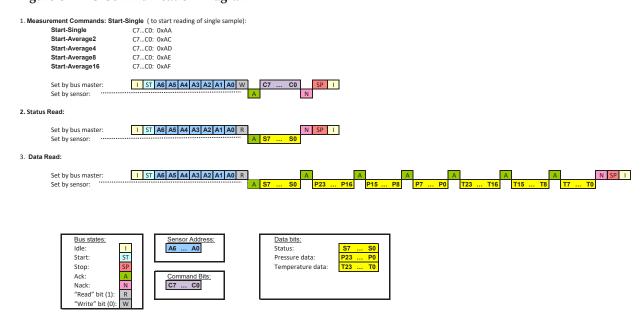

Slave address (An): The I2C-bus requires a unique address for each device. The DLLR sensor has a preconfigured slave address (defined by device option, see Table 9). After setting a START condition the master sends the address byte containing the 7 bit sensor address followed by a data direction bit (R/W). A "0" indicates a transmission from master to slave (WRITE), a "1" indicates a device-to master request (READ).

Acknowledge (A or N): Data is transferred in units of 8 bits (1 byte) at a time, MSB first. Each data-receiving device, whether master or slave, is required to pull the data line LOW to acknowledge receipt of the data. The Master must generate an extra clock pulse for this purpose. If the receiver does not pull the data line down, a NACK condition exists, and the slave transmitter becomes inactive. The master determines whether to send the last command again or to set the STOP condition, ending the transfer.

<u>DATA valid (Dn):</u> State of data line represents valid data when, after a START condition, data line is stable for duration of HIGH period of clock signal. Data on line must be changed during LOW period of clock signal. There is one clock pulse per data bit.

<u>STOP condition (P):</u> LOW to HIGH transition of the SDA line while clock (SCL) is HIGH indicates a STOP condition. STOP conditions are always generated by the master.

Figure 3 - I2C Communication Diagram

SPI Interface

SPI Command Sequence

As with the I2C interface configuration, the part enters Idle state after power-up, and waits for a command from the SPI master. To start a measurement cycle, one of the 3- byte Measurement Commands (see Table 1) must be issued by the master. To start a memory read operation, the memory read request (see Table 3) must be sent. The data returned by the sensor during this command request consists of the Status Byte followed by two undefined data bytes.

On successful decode of a measurement command, the EOC pin is set Low as the core goes into Active state for measurement and calculation. When complete, updated sensor data is written to the output registers, and the core goes back to the Idle state. The EOC pin is set to a High level at this point, and the Busy status bit is set to 0. At any point during the Active or Idle periods, the SPI master can request the Status Byte by sending a Status Read command (a single byte with value 0xF0).

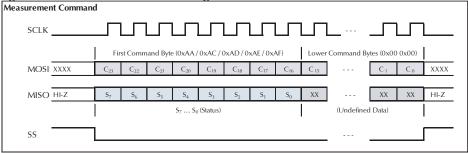

As with the I2C configuration, a Busy bit of value 0 in the Status Byte or a high level on the EOC pin indicates that a valid data set may be read from the sensor. The Data Read command must be sent from the SPI master (The first byte of value 0xF0 followed by 6 bytes of 0x00). For memory read operations, see Table 4 for reading back the result.

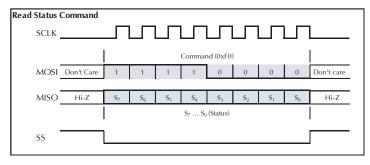

NOTE: Sending commands that are not defined in Tables 1, 3, or 4 will corrupt sensor operation.

SPI Bus Communications Overview

The sequence of bits and bus signals are shown in the following illustration (Figure 4). Refer to Figure 5 in the Interface Timing Diagram section for detailed timing data.

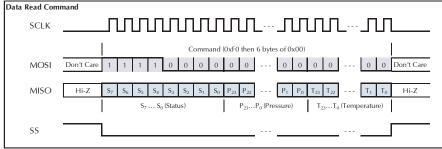

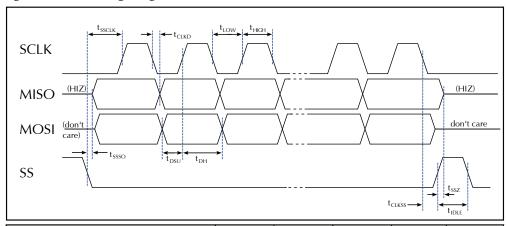

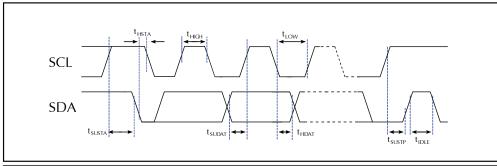

Figure 5 - SPI Timing Diagram

PARAMETER	SYMBOL	MIN	TYP	MAX	UNITS
SCLK frequency (1)	fsclk	0.05	-	5	MHz
SS low to first clock edge	tssclk	120	-	-	ns

Bus idle time	tidle	2.0	-	-	us

Extended Compensation Instructions

DLLR Series sensors have internal memory locations containing extended compensation coefficients. For optimal accuracy of pressure readings, system designers can use these values to apply an additional 3rd-order error-correction adjustment to data delivered from the sensor, as well as additional temperature compensation.

Theory of Extended Compensation:

The four linearity coefficients are obtained for each sensor at the factory by a 3rd order minimization solution to

```
Error = Pref - (POut + f(POut)),
(1)
```

Pref is the true pressure applied;

POut is the sensor output;

f(POut) is a cubic correction function, Ax^3+Bx^2+Cx+D .

Then

(2) **Pcorr = POut + f(POut)** as the linearity-corrected pressure value.

For improved accuracy over temperature, residual temperature-dependent errors are minimized by the term:

```
TCadj = (1 - (E * 2.5 * | 0.5 - Pcorr |)) * (T - Tref) * TC50
```

where:

```
TC50 = TC50H/TCKscale for T > Tref
TC50 = TC50L/TCKscale for T < Tref
```

and:

```
TCKscale = 100 * 100 *134218
```

This represents the possible range of temperature-dependent error, scaled to temperature counts.

Then

Pcomp = Pcorr - Tcadj (4)

for the final optimized pressure value. This is used in the *Pressure Output Transfer Function* on Page 4, to obtain pressure in appropriate units.

Implementation: How to use:

On system startup:

Read the seven coefficients (A, B, C, D, E, TC50H, & TC50L) from sensor EEPROM, using the command sequence described in the datasheet section 'Digital Interface Command Formats'.

A, B, C & D are 32-bit signed integers, representing a scaled magnitude from -1.0 to +1.0.

E, TC50H, & TC50L are 8-bit signed integers, representing a scaled magnitude from -1.0 to +1.0.

Code Example:

Declarations:

```
// I2C Input, output buffers:
unsigned char inbuf[32] = \{0\}, outbuf[32] = \{0\};
// ---- DLLR Coefficients ----
float DLLR_A = 0.0, DLLR_B = 0.0, DLLR C = 0.0, DLLR D = 0.0;
float DLLR E = 0.0, TC50H = 0.0, TCH50L = 0.0;
int32 t i32A = 0, i32B = 0, i32C = 0, i32D = 0,
int8 t i8E = 0, i8TC50H = 0, i8TC50L = 0;
int8 t success = 0;
                                          // I2C communication status
// default sensor I2C address:
uint8 t ui8Address = 0x29;
```

```
After sensor power-on, read EEPROM coefficient values, convert signed 32-bit integers to Float:
       outbuf[0] = 47;
                                                               // Address of A high word
       success = DUT I2C Write(ui8Address, outbuf, 1);
                                                               // 1-byte request
       Wait ms(20);
                                                              // EEPROM access time
       // Read returns [Status][MSB][LSB]:
       success = DUT I2C Read(ui8Address, inbuf, 3);
                                                              // EEPROM result
       i32A = (inbuf[1] << 24) | (inbuf[2] << 16);
                                                              // Assemble MSBs
       outbuf[0] = 48;
                                                              // Address of A low word
       success = DUT_I2C_Write(ui8Address, outbuf, 1);
                                                              // 1-byte request
                                                              // EEPROM access time
       Wait ms(20);
       success = DUT I2C Read(ui8Address, inbuf, 3);
                                                              // EEPROM result
       i32A = ((inbuf[1] << 8) | (inbuf[2]));
                                                              // LSBs, for int32
       // convert to float, normalized to \pm- 1.0:
       DLLR_A = ((float)(i32A))/((float)(0x7FFFFFFF));
Repeat the EEPROM reading process, for B, C, D:
       outbuf[0] = 49;
       success = DUT I2C Write(ui8Address, outbuf, 1);
       Wait ms(20);
       success = DUT I2C Read(ui8Address, inbuf, 3);
       i32B = (inbuf[1] << 24) | (inbuf[2] << 16);
       outbuf[0] = 50;
       success = DUT I2C Write(ui8Address, outbuf, 1);
       Wait ms(20);
       success = DUT_I2C_Read(ui8Address, inbuf, 3);
       i32B = ((inbuf[1] << 8) | (inbuf[2]));
      DLLR_B = (float)(i32B)/(float)(0x7FFFFFFF);
       outbuf[0] = 51;
       success = DUT I2C Write(ui8Address, outbuf, 1);
       Wait ms(20);
       success = DUT I2C Read(ui8Address, inbuf, 3);
       i32C = (inbuf[1] << 24) | (inbuf[2] << 16);
       outbuf[0] = 52;
       success = DUT I2C Write(ui8Address, outbuf, 1);
       Wait ms(20);
       success = DUT I2C Read(ui8Address, inbuf, 3);
       i32C \mid = ((inbuf[1] << 8) \mid (inbuf[2]));
      DLLR_C = (float)(i32C)/(float)(0x7FFFFFFF);
       outbuf[0] = 53;
       success = DUT I2C Write(ui8Address, outbuf, 1);
       Wait ms(20);
       success = DUT I2C Read(ui8Address, inbuf, 3);
      i32D = (inbuf[1] << 24) | (inbuf[2] << 16);
       outbuf[0] = 54;
       success = DUT_I2C_Write(ui8Address, outbuf, 1);
       Wait ms(20);
       success = DUT I2C Read(ui8Address, inbuf, 3);
       i32D \mid = ((inbuf[1] << 8) \mid (inbuf[2]));
       DLLR_D = (float)(i32D)/(float)(0x7FFFFFFF);
```

Now read the 8-bit coefficients TC50H, TC50L, and E, converting signed 8-bit integers to float:

```
outbuf[0] = 55;
success = DUT I2C Write(ui8Address, outbuf, 1);
Wait ms(20);
success = DUT I2C Read(ui8Address, inbuf, 3);
i8TC50H = inbuf [1];
                                                // High Byte,
i8TC50L = inbuf [2];
                                                // Low Byte
// convert to float, normalized to \pm/- 1.0:
TC50H = (float)(i8TC50H)/(float)(0x7F);
TC50L = (float)(i8TC50L)/(float)(0x7F);
outbuf[0] = 56;
success = DUT I2C Write(ui8Address, outbuf, 1);
Wait ms(20);
success = DUT I2C Read(ui8Address, inbuf, 3);
i8E = inbuf [2];
                                                // Low Byte
DLLR E = (float)(i8E)/(float)/(0x7F);
```

These floating-point values are used in adjustments applied to each reading, described as follows:

Correction applied to each reading:

For each pressure value read from the sensor (POut), calculate

```
PComp = POut + A*POut<sup>3</sup> +B*POut<sup>2</sup> + C*POut +D - TCadj.
(If the application operates in an environment consistently near 25C, TCadj is an optional term.)
```

Example:

The sensor 24-bit pressure and temperature values are now in the I2C input buffer, preceded by the status byte. That is, inbuf[0] = Status Byte, inbuf[1], [2], [3] contain the pressure value, and inbuf[4], [5],[6] contain temperature.

Now, apply the corrective adjustments:

Declarations & definitions:

```
// constants:
const int32_t Tref_Counts = 8724019; // temperature counts at 25C
const float TCKScale = 100.0 * 100.0 * 134218.0 // scale TC50 to 0.6% FS0
float AP3, BP2, CP, Corr, Pcorr, Pdiff, TCadj, TC50, Pnfso, Tcorr, Pcorrt;
int32_t iPraw, Tdiff, iTemp, iPCorrected;
uint32_t PComp;
```

First, correct for linearity, as in Equation (2):

```
// Convert unsigned 24-bit pressure value to signed +/- 23-bit:
iPraw = (inbuf[1]<<16) + (inbuf[2]<<8) + inbuf[3] - 0x800000;
// Convert signed 23-bit value to float, normalized to +/- 1.0:
Pnorm = (float) iPraw; // cast to float
Pnorm /= (float) 0x7FFFFFF;</pre>
```

At this point, Pcorr represents the linearity-corrected pressure, optimized at 25C temperature. For room-temperature applications, this may be sufficient compensation.

Converting back to the sensor native format of unsigned 24-bit integer:

The Pressure Output Transfer Function on Page 4 can then be applied, using iPcorr as the value for Pdig.

For systems exposed to temperatures significantly above or below 25C, additional temperature compensation may be applied, as shown below:

```
// Compute difference from reference temperature, in sensor counts: iTemp = (inbuf[4] << 16) + (inbuf[5] << 8) + inbuf[6]; // 24-bit temperature Tdiff = <math>iTemp - Tref Counts; // see constant defined above.
```

Re-normalize the linearity-corrected pressure from ± 1.0 to [0-1.0):

Pnfso = (Pcorr + 1.0)/2.0;

Now, the temperature-dependent adjustment as a function of pressure and temperature difference from reference values as in Equation (3):

```
Tcorr = (1.0 - (DLLR E * 2.5 * Pdiff)) * Tdiff * TC50 / TCKScale;
```

this adjustment is applied to the linearity-corrected value, as in Equation(4):

```
PCorrt = Pnfso - Tcorr; // corrected P: float, [0 to +1.0)
```

Re-normalize back to unsigned 24-bit value, finishing Equation (4):

```
Pcomp = (uint32_t) (PCorrt * (float) 0xFFFFFF);
```

Start next sensor reading:

Convert to pressure units:

The **Pcomp** result represents the corrected output of the sensor, to be used in the Pressure Output Transfer Function as Pdig when computing pressure in calibrated measurement units.

For illustration, if the sensor has a differential calibrated range of +/- 10 inH2O, $P_{inH2O} = 1.25 * ((Pcomp - (0.5 * 2^{24}))/ 2^{24}) * 2 * 10 inH2O$

where the 1.25 factor represents the scaling of full-scale output to the calibrated range (Output at Minimum pressure = 10% of full scale, output at Maximum pressure = 90%); and division of (Pcomp $- 2^{23}$) by 2^{24} resulting in a +/-0.5 scaling value re-scaled by the units 2x multiplier.

If a reading from this sensor results in Pcomp = 9145890 counts,

P_{inH2O} = 1.25 * ((9145890 – 8388608)/ 16777216) * 20 inH2O = 1.1284 inH2O

For a compensated reading of Pcomp = 3000000 counts,

P_{inH2O} = 1.25 * ((3000000 - 8388608)/ 16777216) * 20 inH2O = -8.0297 inH2O

How to Order

Refer to Table 8 for configuring a standard base part number which includes the pressure range, package and temperature range. Table 9 shows the available configuring options. The option identifier is required to complete the device part number. Refer to Table 10 for the available device packages.

Example P/N with options: DLLR-L10D-E1NS-C-NAV6

Table 8 - How to configure a base part number

	SERIES	PRESSURE RANGE							PACKAGE			Г	TEMPI	ERATURE RANGE
